(Received August 2002 )

In this work we describe some aspects of the dynamics of the Cahn-Hilliard equation. In particular, we consider the dynamics of "bubble" solutions that is spherical interfaces which move superslowly towards the boundary without changing their shape. We show for the Cahn-Hilliard that the bubble drifts towards the closest point on the boundary provided it is sufficiently small. This is contrasted with the related mass conserving Allen-Cahn equation where size is not an issue.

1 Introduction

We are concerned with the Cahn-Hilliard equation

\[
\begin{cases}
  u_t = -\Delta[\epsilon^2 \Delta u - W'(u)], & x \in \Omega \\
  \frac{\partial u}{\partial n} = \frac{\partial \Delta u}{\partial n} = 0, & x \in \partial \Omega
\end{cases}
\]

(1.1)

with \( \Omega \subset \mathbb{R}^N \), a smooth bounded domain, \( \frac{\partial}{\partial n} \) the outward Neumann derivative, \( 0 < \epsilon << 1 \) a small parameter and \( W \) a double well potential. This equation is widely accepted as a model that describes the space-time evolution of the concentration \( u(x,t) \) of a binary alloy that originally homogeneous with concentration \( \bar{u} \) separates in two coexisting phases with concentrations \( u_1, u_2, u_1 < \bar{u} < u_2 \). The separation phenomena begins after rapid quenching of the alloy below the curve of miscibility. Above this curve the homogeneous phase with concentration \( \bar{u} \) is stable in thermodynamic equilibrium. Below the curve of miscibility the homogeneous phase becomes thermodynamically unstable and thermodynamical equilibrium correspond to two equally favoured phases with concentration \( u_1, u_2 \). Therefore after rapid quenching a complicated separation phenomenon that may includes nucleation and spinodal decomposition begins. We refer to [7], [8], [11], [16], [19], [20] for physical background and numerical studies. The Cahn-Hilliard equation can be viewed [12] as the gradient system corresponding to the free energy functional

\[
\begin{align*}
  J_\epsilon(u) &= \int_\Omega \left( \frac{\epsilon^2}{2} |\nabla u|^2 + W(u) \right) dx, \\
  u &\in \{ v \in H^1(\Omega) : \frac{1}{|\Omega|} \int_\Omega v dx = \bar{u} \}
\end{align*}
\]

(1.2)

where \( \Omega \subset \mathbb{R}^N \) is a smooth bounded domain which represents the container of the alloy and \( |\Omega| \) is the measure of \( \Omega \), \( u \) is the concentration and \( W \) is a double well potential with two equal nondegenerate minima
at \( u = \pm 1 \). A typical example is \( W(u) = \frac{1}{4}(u^2 - 1)^2 \). The Cahn-Hilliard preserves the average concentration
\[
\frac{1}{|\Omega|} \int_\Omega u(x, t) dx = \overline{u}
\]
where \( \overline{u} \) is independent of \( t \). The conservation of \( \overline{u} \) exposes the fact that the amount of the two components of the alloy contained in the vessel does not change during separation. The gradient dynamics associated to the functional (1.2) under the constraint (1.3) depends on the choice of the Hilbert space \( H \) with respect to which the gradient is computed. For instance, if \( H = L^2_0(\Omega) = \{ \phi \in L^2(\Omega), \int_\Omega \phi = 0 \} \) then instead of (1.1) one obtains the nonlocal Allen-Cahn equation
\[
\begin{cases}
  u_t = \varepsilon^2 \Delta u - (W'(u) - \frac{1}{|\Omega|} \int_\Omega W'(u) dx), & \text{in } \Omega \\
  \frac{\partial u}{\partial n} = 0, & \text{on } \partial \Omega
\end{cases}
\]
(1.4)
The functional \( J_\varepsilon(u) \) is the sum of the bulk free energy \( \int_\Omega W(u) dx \) and of the term \( \int_\Omega \frac{\varepsilon^2}{2} |\nabla u|^2 \) which models the contribution of the surface energy. The \( W \) term favors functions that take values close to its minima. We call such functions layered. We call interfaces the zero level sets of such a function, and we call states, the values close to \( \pm 1 \), that \( u \) takes almost uniformly away from the interface. The parameter \( \varepsilon > 0 \) is assumed to be very small \( \varepsilon \ll 1 \) where \( \varepsilon \) is a measure of the relative importance of surface energy to bulk free energy. By direct calculation one can verify that along solution (1.1) satisfies
\[
\frac{1}{|\Omega|} \int_\Omega u(t) dx = \overline{u}, \quad \frac{d}{dt} J_\varepsilon(u(t)) \leq 0
\]
(1.5)
As mentioned by Fife [12], the Cahn-Hilliard equation is the gradient dynamic with respect to the Hilbert space \( \mathcal{H} \) which is the completion of \( L^2_0 = \{ v \in L^2(\Omega)/ \int_\Omega v dx = 0 \} \), the subspace of \( L^2(\Omega) \) of functions with zero average with respect to the inner product
\[
(v_1, v_2)_{\mathcal{H}} = ((-\Delta)^{-1} v_1, (-\Delta)^{-1} v_2)_{L^2(\Omega)}
\]
(1.6)
where \((-\Delta)^{-1}\) is the self-adjoint positive operator defined by \( w = (-\Delta)^{-1} v \) and \( w \) is the unique solution of the problem
\[
\begin{cases}
  -\Delta w = v \\
  \frac{\partial w}{\partial n} = 0 \\
  \int_\Omega w dx = \int_\Omega v dx = 0
\end{cases}
\]
(1.7)
In [1] it was established that the Cahn-Hilliard in higher space dimensions supports superslow solutions called "bubble" solutions. These correspond to an approximately spherical interface drifting slowly towards the boundary, without changing its shape. Solutions like that are typical of the final stages of evolution for general initial conditions. The order of magnitude of the speed of the "bubble" is
\[
\dot{\xi} = O(e^{-\frac{c}{\varepsilon}})
\]
(1.8)
where \( \xi = \xi(t) \) here stands for the center of the bubble and \( d\xi = d(\xi, \partial \Omega) - \rho \) the distance of the bubble from the boundary \( \partial \Omega \). One of the remarkable features of this dependence of the time scale on \( \varepsilon \) is that changing for example \( \varepsilon \) by a factor of 100 slows down the process by a factor of \( e^{100} \), and so make it practically still.
Motion of Bubbles towards the Boundary for the Cahn-Hilliard Equation

The phenomenon of superslow motion in a related context, in 1d, was first derived in [18]. An explicit, and rigorous, characterization of metastability for the Allen-Cahn equation was done in the pioneering works of Carr-Pego [9] and Fusco-Hale [14]. For the Cahn-Hilliard equation, metastable motion was proved in [2], [6] and also [15]. Later, an explicit, rigorous analysis yielding ODE’s is given in Bates and Xun [4]. A formal analysis comparing the ODE’s for the Cahn-Hilliard equation, viscous Cahn-Hilliard, and constrained Allen-Cahn equation is given in Sun and Ward [22]. In [1] it was stated without proof that for the Cahn-Hilliard the bubble solution is drifting roughly towards the closest point on the boundary. Subsequently in [23] this statement for the bubble solutions of the related mass conserving Allen-Cahn equation is established while this model was first introduced in [21].

\[
\begin{aligned}
&\left\{ \begin{array}{l}
u_t = \epsilon^2 \Delta u - \frac{1}{\rho} \int_{\Omega} W'(u) dx, \quad \text{in } \Omega \\
\frac{\partial u}{\partial n} = 0, \quad \text{on } \partial \Omega
\end{array} \right.
\end{aligned}
\]  

(1.9)

Slow Motion for (1.9) was established in [3]. Ward established for (1.9) the following formula for the speed with careful formal asymptotics

\[
\hat{\xi} \sim \frac{\epsilon N \alpha^2 \nu^2}{\omega N \beta} \int_{\partial \Omega} \rho^{-1-N} e^{-2\nu e^{-1}(r-\rho)} \hat{r}[1 + \hat{r} \hat{n}] \hat{r} \hat{n} dS
\]

(1.10)

where \( r = |x - \xi|, \hat{r} = \frac{x - \xi}{r}, \hat{n} \) denotes the unit vector on \( \partial \Omega \), \( \omega_N \) is the measure of the surface of the unit sphere in \( \mathbb{R}^N \), and \( \alpha, \nu, \nu_\epsilon \) positive constants. Analysing then the integral term by Laplace’s method the following expression is obtained

\[
\hat{\xi} \sim \frac{2 \epsilon N \alpha^2 \nu^2}{\omega N \beta} (\pi \epsilon)^{\frac{N-1}{2}} K(r_m) e^{-2\nu e^{-1}(r_m-\rho)}, \quad \text{as } \epsilon \to 0
\]

(1.11)

where \( K(r_m) = (1 - \frac{r_m}{R_1})^{-\frac{1}{2}} (1 - \frac{r_m}{R_2})^{-\frac{1}{2}} \cdots (1 - \frac{r_m}{R_{N-1}})^{-\frac{1}{2}}, R_j \geq 0 \), for \( j = 1, \ldots, N-1 \) are the principal radii of curvature and \( r_m \) denotes the minimum distance to the \( \partial \Omega \). In the present work by building on [1] and Ward [23] we derive for the Cahn-Hilliard (1.1) the expression:

\[
\hat{\xi} \sim \left( \frac{\partial u^\xi}{\partial \xi_i^\xi}, \frac{\partial u^\xi}{\partial \xi_j^\xi} \right)^{-1} \frac{\epsilon N \alpha^2 \nu^2}{\omega N \beta} \int_{\partial \Omega} \rho^{-1-N} e^{-2\nu e^{-1}(r-\rho)} \hat{r}[1 + \hat{r} \hat{n}] \hat{r} \hat{n} dS
\]

(1.12)

with \( u^\xi \) a layered function which is near a step function and is defined in section 2

\[
\hat{\xi} \sim (\Gamma^\xi)^{-1} \frac{\epsilon N \alpha^2 \nu^2}{\omega N \beta} \int_{\partial \Omega} \rho^{-1-N} e^{-2\nu e^{-1}(r-\rho)} \hat{r}[1 + \hat{r} \hat{n}] \hat{r} \hat{n} dS
\]

(1.13)

where \( \Gamma^\xi \) is the matrix which at principal order is given by

\[
\Gamma^\xi_{ij} = \rho^{2N-2} M \int_{S^{N-1}} \int_{S^{N-1}} G(\rho u + \xi, \rho v + \xi) < u, e_i > < v, e_j > dudv
\]

(1.14)

where \( M = \frac{\omega_N}{N-2} [U(\infty) - U(-\infty)]^2 \) is a constant, \( u, v \in S^{N-1}, \{ e_i \}_{i=1}^N \) is the standard basis of \( \mathbb{R}^N \), \( \rho \) is the bubble radius, \( \xi \) is the center of the bubble and \( G(x,y) \) is the fundamental solution of the problem (3.6) below. The function \( G(\rho u + \xi, \rho v + \xi) \) depends on a global way from the shape of \( \partial \Omega \) and \( (\rho, \xi) \). Therefore \((\Gamma^\xi)^{-1}\) is in general far from a multiple of the identity or even from a diagonal matrix and cannot be computed explicitly. A consequence of this fact is that under the Cahn-Hilliard dynamic, the bubble drifts towards the
boundary of $\Omega$ following a curved path and not a straight line as in the case of the conserved Allen-Cahn. Moreover, the point where the bubble hits the boundary is not in general the closest one. In the special case $\Omega = \{(x_1, x_2)/x_1 > 0, x_2 > 0\} \subset \mathbb{R}^2$, using the method of images $G(\rho u + \xi, \rho v + \xi)$ can be computed and thus derive information on the dependence of $\xi$ on $\xi = (\xi_1, \xi_2)$. In the following, we perform a rigorous asymptotic analysis of the matrix $\Gamma^\xi$ under the assumption that the radius of the bubble is very small: $\rho \ll 1$ and show that for the Cahn-Hilliard the bubble drifts towards the closest point on the boundary, provided it is sufficiently small, (Fig. 1). Our analysis of $\Gamma^\xi$ for $\rho \ll 1$ shows that to principal order in $\rho$, $\Gamma^\xi$ is a multiple of the identity matrix. This is to be expected because if $N(|x - y|)$ is the fundamental solution of $\Delta$ we have

$$G(\rho u + \xi, \rho v + \xi) = N(\rho|x - y|) + \gamma(\rho u + \xi, \rho v + \xi)$$

for some smooth function $\gamma(x, y)$. This expression of $G$ shows that $G$ depends on the geometry of $\partial \Omega$ only through $\gamma$ and on the other hand for $\rho \ll 1$ we have

$$\int_{S^{N-1}} \int_{S^{N-1}} \gamma(\rho u + \xi, \rho v + \xi) < u, e_i > < u, e_j > dudv \simeq \gamma(\xi, \xi) \int_{S^{N-1}} \int_{S^{N-1}} < u, e_i > < v, e_j > dudv = 0$$

This should be contrasted with Ward’s result for (1.9) where size is not an issue. Besides the Cahn-Hilliard and the conserved Allen-Cahn there are also other situations where slow motion occurs. For instance in [10], [17] it has been shown for the shadow Gierer-Meinhardt model that the spike shape is stable and the single interior spike moves superslowly towards the boundary. There are systems where the boundary repeal each other. Underlying all these results, there is the stability of a stationary radial solution in $\mathbb{R}^N$, something which is impossible for a second order scalar parabolic equation but becomes possible for a system when conservation takes place.

![Figure 1. The bubble drifts towards the closest point on the boundary](image)

**2 Preliminaries**

**a)** The following proposition which was proved in [1] concerns the existence of radial solutions of

$$-\Delta[\Delta u - W'(u)] = 0, \quad \text{on} \quad \mathbb{R}^N$$

(2.1)

or equivalently

$$\Delta u - W'(u) = \sigma(\rho), \quad \text{on} \quad \mathbb{R}^N$$

(2.2)
where $\epsilon$ is scaled out.

**Proposition 2.1**

A. There exists a number $\bar{\rho} > 0$ and smooth functions $\sigma : (\bar{\rho}, \infty) \to \mathbb{R}$, $U^* : [0, \infty) \times (\bar{\rho}, \infty) \to \mathbb{R}$, such that for each $\rho \in (\bar{\rho}, \infty)$, $\sigma(\rho)$ and $u(x, \rho) = U^*(|x|, \rho)$ satisfy equation (2.2). Moreover, $U^*(r, \rho)$ is increasing in $r$ and

(i) $\sigma(\rho) = X\rho^{-1} + O(\rho^{-2})$,

(ii) $U^*(\rho, \rho) = O(\rho^{-1})$,

(iii) $1 + U^*(0, \rho) = O(\rho^{-1})$,

(iv) $\lim_{r \to \infty} U^*(r, \rho) = \alpha(\rho)$,

where $X > 0$ is a constant and $\alpha(\rho)$ is the root near 1 of the equation $W'(u) + \sigma(\rho) = 0$.

(v) $\alpha(\rho) - U^*(r, \rho) = O(e^{-\nu(\rho)(r-\rho)})$, $\nu(\rho) = (W''(\alpha(\rho)))^{\frac{1}{2}}$,

and similar exponential estimates hold for the derivatives of $U^*$ with respect to $r$. We expect that, as $\rho \to \infty$, $U^*(s) = U^*(s-\rho, \rho)$ tends to $U$, the unique bounded solution of $U'' - W'(U) = 0$, $\lim_{s \to \pm \infty} U(s) = \pm 1$, $U(0) = 0$.

B. There is a number $C > 0$, independent of $\rho$, such that the functions $\sigma, U^*$ satisfy the following estimates:

(vi) $\sigma'(\rho) = X\rho^{-2} + O(\rho^{-3})$,

(vii) $U^*(r, \rho) = U(r - \rho) + V(r - \rho, \rho) + O(\rho^{-2})$, $r - \rho \in [-C\rho, \infty)$,

$U^*_{\rho}(r, \rho) = -\dot{U}(r - \rho) + V_{\rho}(r - \rho, \rho) + O(\rho^{-3})$, $r - \rho \in [-C\rho, \infty)$

where

$$V(r, \rho) = X\rho^{-1}\int_{-\infty}^{\infty} G(r, s)ds, \quad X = \int_{-\infty}^{\infty} \dot{U}^2 \int_{-\infty}^{\infty} \dot{U}$$

Moreover,

(viii) $\int_{-\infty}^{\infty} W''(U)\dot{U}^2V = 0$

**b) The Fundamental Block**

The “Bubble” $u^\xi(x)$

---

Figure 2. Radial solutions of (2.1)
By means of Proposition 2.1 we can associate with each \( \xi \in \Omega_{\rho+\delta} = \{ \xi | d(\xi, \partial \Omega) - \rho > \delta \} \) a function 
\( u^\xi : \Omega \to \mathbb{R} \) with the following properties:

(a) It is an almost stationary solution of the Cahn-Hilliard equation in the sense that it fails to satisfy the equation, or the boundary conditions, by terms which are of the order \( O(e^{-c/\epsilon}) \);

(b) It jumps from near \(-1\) to near 1 in a thin layer of size of order \( \epsilon \) around the circle of radius \( \rho \) and center \( \xi \). For \( \epsilon \ll 1 \) we set 
\[
\int_{\Omega} u^\xi = \int_{\Omega} u^{\xi_0}, \quad \forall \xi \in \Omega_{\rho+\delta}
\] (2.3)

We choose \( \xi_0 \) to be a point of maximal distance from \( \partial \Omega \).

Lemma 2.2, ([1])

The number \( a_\xi \) is uniquely determined by the condition (2.3) and the assumption \( \alpha_\xi = 0 \).
Moreover, 
\[
0 \leq \alpha^\xi < C e^{-(\nu_\epsilon/\epsilon)d^\epsilon}, \quad \nu_\epsilon = \nu(\rho/\epsilon),
\]
where \( d(\xi, \partial \Omega) - \rho \). Similar estimates hold for derivatives of \( \alpha^\xi \) with respect to \( \xi_i, \ i = 1, 2 \).

c) The Manifold

In this section, we review quickly the main geometric approach developed in [1] following the work in [14] and [9] and building on [1] and [23] we derive the asymptotics in (1.13). The Motion of the bubble corresponds to the dynamics of the Cahn-Hilliard equation as an \( N \)-dimensional invariant manifold \( M^\epsilon_\rho \). This manifold turns out to be represented as a graph over the manifold of bubbles

\[
M^\epsilon_\rho = \{ u^\xi/\xi \in \Omega_{\rho+\delta} \}
\] (2.4)

where

\[
\Omega_{\rho+\delta} = \{ \xi \in \Omega/(\xi, \partial \Omega) > \rho + \delta \}, \quad u^\xi = u^\xi(x)
\]

\[
M^\epsilon_\rho = \{ u^\xi + v^\xi/\xi \in \Omega_{\rho+\delta} \}, \quad v^\xi \perp T_{u^\xi/\rho}
\]

where \( v^\xi = v^\xi(x) \) is small and orthogonal to the tangent space to \( M^\epsilon_\rho \) in the Hilbert sense (1.6). Writing the Cahn-Hilliard equation in the abstract form

\[
u_t = \mathcal{L}(u)
\] (2.5)

we can restate invariance equivalently as the condition of tangency of the vector field \( \mathcal{L} \) to \( M^\epsilon_\rho \),

\[
\mathcal{L}(u^\xi + v^\xi) = c_i(\xi) \cdot \frac{\partial}{\partial \xi_i}(u^\xi + v^\xi)
\]

\[
v^\xi \perp \frac{\partial u^\xi}{\partial \xi_1}, \ldots, \frac{\partial u^\xi}{\partial \xi_n}
\] (2.6)

where \( c_i(\xi) \) is the \( i \)-th component of the speed, \( \xi = c(\xi) \) and where the summation convention over repeated indices is employed. The Quasi-invariant manifold \( \tilde{M}^\epsilon_\rho \) is an intermediate object between \( M^\epsilon_\rho \) and \( M^\epsilon_\rho \), where
\[ \hat{v}^\xi(x) \text{ is defined via} \]
\[ L(\hat{u}^\xi + \hat{v}^\xi) = \hat{c}_i(\xi) \frac{\partial}{\partial \xi_i} u^\xi \]
\[ \hat{v}^\xi \perp \frac{\partial u^\xi}{\partial \xi_1}, \ldots, \frac{\partial u^\xi}{\partial \xi_n}, \quad \int_\Omega \hat{v}^\xi = 0 \quad (2.7) \]

System for \( \hat{v} \) and \( \hat{c} \) is analysed in [1].

d) The expression of the speed

It follows from theorems proved in [1] that \( ||v^\xi|| = (e^{-\nu_0 d_\xi}) \), \( d_\xi = d(\xi, \partial \Omega) - \rho, \sigma(\xi) = O(e^{-2\nu_0 d_\xi}) \). Utilizing these estimates it follows that the product \( c_i(\xi) \cdot \frac{\partial}{\partial \xi_i} (v^\xi) \) is of the order \( (e^{-2\nu_0 d_\xi}) \) and so it is insignificant with respect to \( e^{-2\nu_0 d_\xi} \). This argument suggests that \( \hat{c}(\xi) \) is a good approximation of \( c(\xi) \). We now proceed to derive an expression for \( \hat{c}(\xi) \).

We rewrite (2.7) in the form
\[
\begin{cases}
\Delta \epsilon^2 \Delta (u^\xi + \hat{v}^\xi) - (W''(u^\xi + \hat{v}^\xi)) = \hat{c}_i(\xi) \frac{\partial}{\partial \xi_i} u^\xi, & \text{in } \Omega \\
\frac{\partial}{\partial n} (u^\xi + \hat{v}^\xi) = 0, & \text{on } \partial \Omega \\
(\frac{\partial}{\partial n}, \hat{v}^\xi)_H = 0, & i = 1, \cdots, N. 
\end{cases} \quad (2.8)
\]

Expanding the equation about \( u \) and making use of
\[ -\Delta \epsilon^2 \Delta u^\xi - W''(u^\xi) = 0 \quad (2.9) \]
we can rewrite (2.8) in the form
\[ L^\xi \hat{v}^\xi + N(\hat{v}^\xi) = \hat{c}_i(\xi) \frac{\partial}{\partial \xi_i} u^\xi \quad (2.10) \]
where
\[ L^\xi = -\Delta \epsilon^2 \Delta - W''(u^\xi)I \]
and \( N \) is the nonlinear term.

Taking the inner product of (2.10) with \( \frac{\partial}{\partial \xi_i} u^\xi =: u^\xi_{\xi_i} \), we obtain
\[ (u^\xi_{\xi_i}, L^\xi \hat{v}^\xi)_H + (u^\xi_{\xi_i}, N(\hat{v}^\xi))_H = \hat{c}_i(u^\xi_{\xi_i}, u^\xi_{\xi_j})_H \quad (2.11) \]

Ignoring the nonlinear term in (2.11)
\[ (u^\xi_{\xi_i}, L^\xi \hat{v}^\xi)_H \simeq \hat{c}_i(u^\xi_{\xi_i}, u^\xi_{\xi_j})_H \]

Utilizing the definition of Hilbert space in (1.6) we obtain
\[ (u^\xi_{\xi_i}, \epsilon^2 \Delta \hat{v}^\xi - W''(u^\xi)\hat{v}^\xi)_L^2 \simeq \hat{c}_i(u^\xi_{\xi_i}, u^\xi_{\xi_j})_H \quad (2.12) \]

From
\[ \epsilon^2 \Delta u^\xi - W''(u^\xi) = \sigma \]
we have
\[ \epsilon^2 \Delta u^\xi_{\xi_i} - W''(u^\xi)u^\xi_{\xi_i} = \frac{\partial \sigma}{\partial \xi_j} \]
and so
\[ \int_{\Omega} \epsilon^2 \Delta u_{\xi} \tilde{v} \, dx - \int_{\Omega} W''(u_{\xi}) u_{\xi} \tilde{v} \, dx = 0 \]
(by \( \int \tilde{v} = 0 \)).
Integrating by parts
\[ \int_{\partial \Omega} \left( \frac{\partial u_{\xi}}{\partial n} \tilde{\nu} - \frac{\partial \tilde{v}}{\partial n} u_{\xi} \right) dS \simeq \tilde{c}_i (u_{\xi_i}, u_{\xi_j}) \mathcal{H} \]  \hspace{1cm} (2.13)
Utilizing now the boundary conditions in (2.13) we obtain
\[ \int_{\partial \Omega} \left( \frac{\partial u_{\xi}}{\partial n} \tilde{\nu} + \frac{\partial u_{\xi}}{\partial n} u_{\xi} \right) dS = \tilde{c}_i (u_{\xi_i}, u_{\xi_j}) \mathcal{H} \]  \hspace{1cm} (2.14)
Finally making use of
\[ \frac{\partial u_{\xi}}{\partial \xi_i} = \frac{\partial u_{\xi}}{\partial x_i} + \frac{1}{\epsilon} \nu \frac{\partial u_{\xi}}{\partial \xi_i} \]  \hspace{1cm} (2.15)
and of the estimates in [1] we can replace the \( \xi \)-derivatives in (2.14) with \( x \)-derivatives without affecting significantly \( \tilde{c}_i \):
\[ \int_{\partial \Omega} \left( \frac{\partial u_{\xi_i}}{\partial n} \tilde{\nu} + \frac{\partial u_{\xi_i}}{\partial n} u_{\xi_j} \right) dS \sim \tilde{c}_i (u_{\xi_i}, u_{\xi_j}) \mathcal{H} \]  \hspace{1cm} (2.16)
Next we will be utilizing some of the asymptotics in [23] for \( x \in \partial \Omega \):
\[ \begin{cases} u_{\xi_i}^\nu = \nu \alpha \frac{\nu}{|x - \xi|} & 1 \frac{\nu}{|x - \xi|} e^{-\nu (|x - \xi| - \nu)} \left[ (x - \xi) + O(\epsilon) \right] \\ \frac{\partial u_{\xi_i}^\nu}{\partial n} = -\nu^2 \frac{\nu}{|x - \xi|} e^{-\nu (|x - \xi| - \nu)} \left[ (x - \xi) \frac{\nu}{|x - \xi|} \tilde{n} + O(\epsilon) \right] \end{cases} \]  \hspace{1cm} (2.17)
For determining \( \tilde{v} \) to principal order, by following Ward we argue that in (2.10) we can ignore the nonlinear term \( \mathcal{N} \) and \( \tilde{c} \) since \( \tilde{c} \sim e^{-\frac{2\nu d}{d}} \). So, (2.10) together with the boundary conditions (2.8) in \( x, y \) coordinates takes the form
\[ \begin{cases} L^\xi v^\xi = 0 \\ \frac{\partial}{\partial n} (u^\xi + \tilde{v}^\xi) = 0 \end{cases} \]  \hspace{1cm} (2.18)
By utilizing canonical coordinates \( (s, \tilde{n}) \) where \( \tilde{n} \) denotes the distance from the boundary and \( s \) the projection on \( \partial \Omega \), \( \frac{\nu}{2} = \eta, \frac{\nu}{2} = \sigma \), (2.18) becomes
\[ \begin{cases} \Delta (\mathcal{N} v^\xi (\sigma, \eta)) - \nu^2 v^\xi = 0 \\ \frac{\partial v^\xi}{\partial n} (\sigma, 0) = \frac{\partial u^\xi}{\partial n} (\sigma, 0), \quad \frac{\partial^2 v^\xi}{\partial n^2} (\sigma, 0) = \frac{\partial^2 u^\xi}{\partial n^2} (\sigma, 0) \end{cases} \]  \hspace{1cm} (2.19)
We seek for a solution in the form \( v^\xi = \tilde{v}^\xi (\eta) \) which decays exponentially as \( \eta \to \infty \). So, from (2.19) we have
\( \tilde{v}(\eta) = k e^{-\nu \eta} \). After determining the constant \( k \), we conclude that
\[ \tilde{v}(\eta) = \frac{\partial u^\xi}{\partial n} \bigg|_{n=0} \frac{1}{\nu} e^{-\nu \eta} \]  \hspace{1cm} (2.20)
Substituting \( \tilde{v} \) from (2.20) and (2.17) into (2.16), we obtain the key formula (1.13). In the remainder of this paper we analyse the matrix \( (\cdot, \cdot) \) and show that for small bubbles this matrix is asymptotically a multiple of the identity.
e) Green’s function
We call a fundamental solution $G(x,y)$ with pole $y$ a Green’s function (for the Neumann problem for the Laplace equation in the domain $\Omega$), if

$$G(x,y) = N(x,y) + \gamma(x,y)$$

for $x \in \Omega, y \in \Omega, x \neq y$ with $N(x,y)$ defined

$$N(x,y) = \psi(r) = \psi(|x - y|)$$

$$\psi(r) = \begin{cases} r^{2-N} & \text{for } N > 2 \\
\frac{\log x}{2\pi} & \text{for } N = 2. \end{cases}$$

where $G$ is a modified Green’s function for the Laplacian with Neumann boundary condition and satisfies (3.6) below and $\gamma(x,y)$ for $y \in \Omega$ is a solution of $\Delta \gamma = 0$, of class $C^2(\bar{\Omega})$ for which $G(x,y) = 0$ for $x \in \Omega, y \in \Omega$.

3 Analysis of the matrix $(\frac{\partial u^\xi}{\partial \xi_i}, \frac{\partial u^\xi}{\partial \xi_j})^{-1}$

As it was mentioned in the introduction the purpose of this work is to establish that small bubbles drift towards the closest point on the boundary. So, the analysis of the matrix above is essential and the main ideas of its rigorous analysis can be described as follows: We are interested in obtaining the following estimate

$$\alpha_{ij}^\epsilon = \left( \frac{\partial u^\xi}{\partial \xi_i}, \frac{\partial u^\xi}{\partial \xi_j} \right)_{\mathcal{H}} = C \rho^N \delta_{ij} + O(\rho^{2N-1}) + O(\frac{\rho^2}{\epsilon}) + O(e^{-\frac{c}{\epsilon}}) \quad (\ast)$$

as $\epsilon \to 0$, and $\rho$ fixed.

We will establish $(\ast)$ in three steps. First, we reduce $u^\xi$ to the heteroclinic, then we reduce $\Omega$ due to symmetry to the ring and finally we reduce the Green’s function to the Newtonian potential. So, the desired result is obtained by calculation.

**Step 1. Reduction to the heteroclinic**

Set

$$a_{i j}^\epsilon = -\frac{1}{\epsilon^2} \int_\Omega \int_\Omega G(x,y) \frac{\partial u^\xi(x)}{\partial \xi_i} \frac{\partial u^\xi(y)}{\partial \xi_j} dxdy \tag{3.1}$$

**Lemma 3.1**

$$a_{i j}^\epsilon = -\frac{1}{\epsilon^2} \int_\Omega \int_\Omega G(x,y) \hat{U}(\frac{|x - \xi| - \rho}{\epsilon}) \hat{U}(\frac{|y - \xi| - \rho}{\epsilon}) \frac{x_i - \xi_i}{|x - \xi|} \frac{y_j - \xi_j}{|y - \xi|} dxdy + O(\frac{\rho}{\epsilon}) + O(e^{-\frac{c}{\epsilon}}) \tag{3.2}$$

where $d_\xi = d(\xi, \partial \Omega) - \rho$.

**Proof**
We recall that
\[ u^\xi(x) = U^\ast\left(\frac{|x - \xi|}{\epsilon}, \alpha^\xi + \rho \right) \] (3.3)

By utilizing Proposition 2.1

\[ U^\ast(r, \rho) = U(r - \rho) + V(r - \rho, \rho) + O(\rho^{-2}), \quad r - \rho \in [-C\rho, \infty) \]
\[ U^\ast_\rho(r, \rho) = -\dot{U}(r - \rho) + V_\rho(r - \rho, \rho) + O(\rho^{-3}), \quad r - \rho \in [-C\rho, \infty) \]

for certain \( C \) independent of \( \rho \)

where

\[ V(r, \rho) = \mathcal{X}\rho^{-1} \int_{-\infty}^{\infty} G(r, s)\,ds, \quad \mathcal{X} = \int_{-\infty}^{\infty} \dot{U}^2 \int_{-\infty}^{\infty} \dot{U} \] (3.4)

where \( G(r, s) \) satisfying the estimate

\[ |G(r, s) + \frac{1}{2\epsilon} e^{-|s - \tau|}| \leq C e^{-|r|} e^{-|s|} \] (3.5)

By setting \( r = |x - \xi|, \ \bar{\rho} = \rho + \alpha^\xi \), then from (3.3) we obtain

\[ \frac{\partial u^\xi}{\partial \xi} = \frac{1}{\epsilon} \frac{\partial U^\ast}{\partial r} \frac{\partial r}{\partial \xi} + \frac{1}{\epsilon} \frac{\partial U^\ast}{\partial \rho} \frac{\partial \rho}{\partial \xi} + O\left(e^{-\epsilon\mathcal{X}}\right) \]

\[ = \frac{1}{\epsilon} \dot{U}\left(\frac{r - \bar{\rho}}{\epsilon}\right) + \frac{1}{\epsilon} V_i\left(\frac{r - \bar{\rho}}{\epsilon}, \frac{\bar{\rho}}{\epsilon}\right) + O\left(\frac{\epsilon^2}{\rho^2}\right) \frac{\partial \rho}{\partial \xi} + O\left(e^{-\epsilon\mathcal{X}}\right) \]

\[ = \frac{1}{\epsilon} \dot{U}\left(\frac{r - \bar{\rho}}{\epsilon}\right) + \frac{1}{\rho} Q_i\left(\frac{r - \bar{\rho}}{\epsilon}\right) + O\left(\frac{\epsilon^2}{\rho^2}\right) \frac{\partial \rho}{\partial \xi} + O\left(e^{-\epsilon\mathcal{X}}\right) \]

where \( Q(r) = \int_{-\infty}^{\infty} G(r, s)\,ds \)

Therefore

\[ a_{ij} = -\frac{1}{\epsilon^2} \int_{\Omega} \int_{\Omega} G(x, y) \dot{U}(\frac{|x - \xi| - \bar{\rho}}{\epsilon}) \dot{U}(\frac{|y - \xi| - \bar{\rho}}{\epsilon}) \frac{x_i - \xi_i}{|x - \xi|} \frac{y_j - \xi_j}{|y - \xi|} \,dxdy \]

\[ + O\left(\frac{1}{\epsilon \rho}\right) \int_{\Omega} \int_{\Omega} G(x, y) \dot{U}(\frac{|x - \xi| - \bar{\rho}}{\epsilon}) Q_i(\frac{|y - \xi| - \bar{\rho}}{\epsilon}) \frac{x_i - \xi_i}{|x - \xi|} \frac{y_j - \xi_j}{|y - \xi|} \,dxdy \]

\[ + O\left(\frac{1}{\rho^2}\right) \int_{\Omega} \int_{\Omega} G(x, y) Q_i(\frac{|x - \xi| - \bar{\rho}}{\epsilon}) Q_j(\frac{|y - \xi| - \bar{\rho}}{\epsilon}) \frac{x_i - \xi_i}{|x - \xi|} \frac{y_j - \xi_j}{|y - \xi|} \,dxdy \]

\[ + O\left(\frac{\epsilon^2}{\rho^2}\right) \int_{\Omega} \int_{\Omega} G(x, y)\,dxdy + \frac{1}{\epsilon} + II + III + IV + O\left(e^{-\epsilon\mathcal{X}}\right) \]

By converting to stretched coordinates

\[ \frac{|x - \xi| - \bar{\rho}}{\epsilon} = \eta, \quad \frac{|y - \xi| - \bar{\rho}}{\epsilon} = \bar{\eta} \]

we easily obtain that

\[ |II| = O\left(\frac{1}{\epsilon \rho}\right) \epsilon^2 = O\left(\frac{\epsilon}{\rho}\right), \quad |III| = O\left(\frac{1}{\rho^2}\right) \epsilon^2 = O\left(\frac{\epsilon^2}{\rho^2}\right). \]
Step 2. Reduction to the ring

Due to radial geometry and the fact that $\hat{U}$ localizes around the boundary of the bubble we can have the following reduction to the ring, $\Omega_\delta = \{ x/|x - \xi| - \rho \leq \delta \}, \delta > 0$.

Lemma 3.2
Consider the problem

$$
\begin{cases}
\Delta y = g(x, y), & x, y \in \Omega, \Omega \text{ bounded } \subset \mathbb{R}^N \\
\frac{\partial y}{\partial n} = 0, & \text{on } \partial \Omega
\end{cases}
$$

Then the following estimate holds true

$$
\|G(x, \cdot)\|_{W^{1,q}} < C
$$

where $C$ is independent of $x$ and $q < \frac{N}{N-1}$.

Proof
We recall a result from [5]. Let $u$ be a weak solution of

$$
\begin{cases}
Lu = f & \text{in } \Omega \\
\frac{\partial u}{\partial n} = g & \text{on } \partial \Omega
\end{cases}
$$

Then we have $u \in W^{1,q}(\Omega)$ for all $1 \leq q < \frac{N}{N-1}$ and

$$
\|u\|_{1,q} \leq C_0(\|f\|_{L^1(\Omega)} + \|g\|_{L^1(\Omega)})
$$

The estimate (3.9) is for functions. We would like to apply it to (3.6). For this purpose we introduce a $\delta$-sequence. Let $f_n \geq 0, f_n \to \delta, \int_{\Omega} f_n = 1$

$$
\begin{cases}
\Delta G_n = f_n - \frac{1}{|\Omega|} \\
\frac{\partial G_n}{\partial n} = 0
\end{cases}
$$

Applying estimate (3.9) to (3.10) we take

$$
\|G_n\|_{W^{1,q}} \leq C\|f_n - \frac{1}{|\Omega|}\|_{L^1} \leq C[\|f_n\|_{L^1} + 1]
$$

$$
\|\nabla G_n\|_{L^q} \leq C, \|G_n\|_{L^q} \leq C
$$

So, by using weak compactness we have

$$\nabla G_n \rightharpoonup \nabla w$$

We pass to the limit in the weak formulation of (3.10) and we obtain

$$
-\int_{\Omega} \nabla G_n \nabla \phi \, dx = \int_{\Omega} (f_n - \frac{1}{|\Omega|}) \phi \, dx
$$

$$
-\int_{\Omega} \nabla w \nabla \phi \, dx = \phi(0) - \int_{\Omega} \frac{1}{|\Omega|} \phi \, dx
$$

It follows that

$$G \equiv w$$
By lower semicontinuity of the norm
\[ G_n^{W^{1,q}} \rightarrow G \]
\[ \liminf ||G_n||_{W^{1,q}} \geq ||G||_{W^{1,q}} \]
So by using (3.11) we conclude that
\[ ||G||_{W^{1,q}} \leq C \]
and the result is obtained.

Note
It should be noted that estimate (3.9) is optimal, in the sense that \( 1 \leq q < \frac{N}{N-1} \) cannot be improved. We can easily check this by taking \( N(x-y) \) which is in \( W^{1,q} \), \( q < \frac{N}{N-1} \) but not in \( W^{1,\frac{N}{N-1}} \). Since \( N(x,y) \) satisfies estimate (3.7) \( \Rightarrow \gamma(x,y) \) satisfies also estimate (3.7).

Lemma 3.3
\[ a_{ij} = -\frac{1}{\epsilon^2} \int_{\Omega} \int_{\Omega} G(x,y) \dot{U} \left( \frac{|x-\xi| - \rho}{\epsilon} \right) \dot{U} \left( \frac{|y-\xi| - \rho}{\epsilon} \right) \cos \theta_i(x) \cos \theta_j(y) \, dx \, dy = \]
where
\[ \cos \theta_i(x) = \frac{x_i - \xi_i}{|x-\xi|}, \quad \cos \theta_j(y) = \frac{y_i - \xi_i}{|y-\xi|} \]

Proof
By utilizing Lemma 3.2 and \( |\dot{U}(\eta)| \leq ce^{-c|\eta|} \) we compute
\[ \int_{\Omega} \int_{\Omega} G(x,y) \dot{U} \left( \frac{|x-\xi| - \rho}{\epsilon} \right) \dot{U} \left( \frac{|y-\xi| - \rho}{\epsilon} \right) \cos \theta_i(x) \cos \theta_j(y) \, dx \, dy = \]
\[ + \int_{\partial \Omega} \left( \int_{\Omega} G(x,y) \dot{U} \left( \frac{|x-\xi| - \rho}{\epsilon} \right) \dot{U} \left( \frac{|y-\xi| - \rho}{\epsilon} \right) \cos \theta_i(x) \cos \theta_j(y) \, dx \right) \, dy \]
\[ + \int_{\partial \Omega} \left( \int_{\Omega} G(x,y) \dot{U} \left( \frac{|x-\xi| - \rho}{\epsilon} \right) \dot{U} \left( \frac{|y-\xi| - \rho}{\epsilon} \right) \cos \theta_i(x) \cos \theta_j(y) \, dy \right) \, dx \]
\[ = I + II + III + IV \]
\[ |I|, |IV| \leq C e^{-c\frac{\rho}{\epsilon}} \]
by Lemma 3.2 and the symmetry of \( G_N \).
So,
\[ |II|, |IV| < Ce^{-c\frac{\rho}{\epsilon}} \quad (3.13) \]
\[
\int_{D \setminus \Omega_s} \left( \int_{\Omega_s} G(x, y) \frac{|x - \xi| - \rho}{\epsilon} \frac{|y - \xi| - \rho}{\epsilon} \cos \theta_i(x) \cos \theta_j(y) dx dy \right) \\
\leq \int_{D \setminus \Omega_s} e^{-\frac{\epsilon^2}{4}} \left( \int_{\Omega_s} |G(x, y)| \left| \frac{|x - \xi| - \rho}{\epsilon} \frac{|y - \xi| - \rho}{\epsilon} \right| dx dy \right) \\
\leq Ce^{-c\frac{\rho}{\epsilon}}, \text{ as before}
\]

So,
\[
|\text{III}| < Ce^{-c\frac{\rho}{\epsilon}} \tag{3.14}
\]

The lemma is established.

**Step 3. Reduction to the Newtonian Potential**

By Lemma (3.2) and the fact that (3.7) holds for the Newtonian Potential (as can be checked by explicit calculation), it follows that it also holds for \( \gamma(x, y) \), where

\[
G(x, y) = N(x, y) + \gamma(x, y)
\]

\( N(x, y) \) is the Newtonian Potential and

\[
\begin{cases}
\Delta \gamma(x, y) = -\frac{1}{\epsilon^2}, & \text{in } \Omega \\
\frac{\partial \gamma(x, y)}{\partial n_x} = -\frac{\partial N(x, y)}{\partial n}, & y \in \partial \Omega \tag{3.15}
\end{cases}
\]

By interior elliptic estimates we obtain

\[
|\partial_x^\alpha \partial_y^\beta \gamma(x, y)| < C \tag{3.16}
\]

(\( \alpha + \beta = 2 \)), for \((x, y) \in \Omega_s \times \Omega_s \).

**Lemma 3.4**

\[
\frac{1}{\epsilon^2} \int_{\Omega_s} \int_{\Omega_s} \gamma(x, y) \frac{|x - \xi| - \rho}{\epsilon} \frac{|y - \xi| - \rho}{\epsilon} \cos \theta_i(x) \cos \theta_j(y) dx dy \leq C \rho^{2N-1} \tag{3.17}
\]

**Proof**

\[
\begin{aligned}
\gamma(x, y) &= \gamma(x, y) - \gamma(\xi, \xi) + \gamma(\xi, \xi) \\
&= \nabla_x \gamma(\xi, \xi)(x - \xi) + \nabla_y \gamma(\xi, \xi)(y - \xi) + O(|x - \xi|^2) + \gamma(\xi, \xi) \\
\end{aligned} \tag{3.18}
\]

We note that

\[
\int_{\Omega_s} \int_{\Omega_s} \gamma(x, y) \frac{|x - \xi| - \rho}{\epsilon} \frac{|y - \xi| - \rho}{\epsilon} \cos \theta_i(x) \cos \theta_j(y) dx dy = 0 \tag{3.19}
\]

and by (3.16)

\[
|\gamma(x, y) - \gamma(\xi, \xi)| \leq C \rho. \tag{3.20}
\]

Hence,

\[
\frac{1}{\epsilon^2} \int_{\Omega_s} \int_{\Omega_s} |\gamma(x, y) - \gamma(\xi, \xi)| \frac{|x - \xi| - \rho}{\epsilon} \frac{|y - \xi| - \rho}{\epsilon} dx dy
\]
\[ \leq C_{\rho} \int_{|y| \leq \frac{1}{4}} \int_{|\tau| \leq \frac{1}{4}} U(\eta)\dot{U}(\eta)(\dot{\epsilon} + \rho)^{N-1}(\dot{\epsilon} \eta + \rho)^{N-1} d\eta d\tau \leq C_{\rho}^{2N-1} \]

and the proof of the lemma is complete.

**Lemma 3.5**

Set
\[ I_{ij} = -\frac{1}{\epsilon^2} \int_{\Omega_1} \int_{\Omega_2} N(|x - y|) U\left(\frac{|x - \xi| - \rho}{\epsilon}\right) U\left(\frac{|y - \xi| - \rho}{\epsilon}\right) \cos \theta_i(x) \cos \theta_j(y) dx \, dy \]  \hfill (3.21)

where \( N(|x - y|) = N(x, y) \)

Then
\[ \lim_{\epsilon \to 0} I_{ij} = C_{\rho}^N \delta_{ij} \]  \hfill (3.22)

**Proof**

We give now the proof of the lemma for \( N=2 \) while the proof for \( N > 2 \) can be found in the appendix.

We have
\[ I_{ij} = -\frac{1}{\epsilon^2} \int_{\Omega_1} \int_{\Omega_2} N(|x - y|) U\left(\frac{|x - \xi| - \rho}{\epsilon}\right) U\left(\frac{|y - \xi| - \rho}{\epsilon}\right) \cos \theta_i(x) \cos \theta_j(y) dx \, dy \]

**Claim 1**

\[ \lim_{\epsilon \to 0} I_{ij} = -4\pi^2 \rho^2 [U(\infty) - U(-\infty)]^2 \int_0^{2\pi} \int_0^{2\pi} \frac{1}{\epsilon^2} \ln|\rho| |e^{i\theta} - e^{i\bar{\theta}}| Q_{ij}(\theta, \bar{\theta}) d\theta d\bar{\theta} \]  \hfill (3.23)

where
\[ Q_{11}(\theta, \bar{\theta}) = \cos \theta \cos \bar{\theta}, \quad Q_{12}(\theta, \bar{\theta}) = \cos \theta \sin \bar{\theta}, \quad Q_{21}(\theta, \bar{\theta}) = \sin \theta \cos \bar{\theta}, \quad Q_{22}(\theta, \bar{\theta}) = \sin \theta \sin \bar{\theta} \]

**Proof**

We show that
\[ \frac{1}{U(\infty) - U(-\infty)} \cdot \frac{1}{2\pi \rho} \cdot \frac{1}{\epsilon} \cdot \dot{U}\left(\frac{|x - \xi| - \rho}{\epsilon}\right) \rightarrow \delta_{\rho}(|x - \xi|) \]

\[ \frac{1}{U(\infty) - U(-\infty)} \cdot \frac{1}{2\pi \rho} \cdot \frac{1}{\epsilon} \cdot \dot{U}\left(\frac{|y - \xi| - \rho}{\epsilon}\right) \rightarrow \delta_{\rho}(|y - \xi|) \]

where \( \delta_{\rho} \) is a \( \delta \)-sequence as \( \epsilon \to 0 \)

Indeed
\[ a) \]
\[ \frac{1}{2\pi \rho} \cdot \frac{1}{\epsilon} \int_{\mathbb{R}^2} \dot{U}\left(\frac{|x - \xi| - \rho}{\epsilon}\right) dx = \frac{1}{2\pi \rho} \int_0^{2\pi} \int_0^{\infty} \frac{1}{\epsilon} \dot{U}\left(\frac{r - \rho}{\epsilon}\right) r \, dr \, d\theta \]

\[ = \frac{1}{2\pi \rho} \int_0^{2\pi} \int_0^{\infty} \dot{U}(\eta)(\epsilon \eta + \rho) \, dr \, d\theta \rightarrow U(\infty) - U(-\infty) \]

(by making the change of variables \( r = |x - \xi|, \quad \eta = \frac{r - \rho}{\epsilon} \))

\[ b) \]
\[ \frac{1}{U(\infty) - U(-\infty)} \frac{1}{2\pi \rho} \cdot \frac{1}{\epsilon} \int_{\mathbb{R}^2} \dot{U}\left(\frac{|x - \xi| - \rho}{\epsilon}\right) g(x) dx \rightarrow \int_{|y - \xi|=\rho} g(y) dy \]
Claim 2

\[ \int_0^{2\pi} \int_0^{2\pi} (\ln \rho)Q_{ij}(\theta, \bar{\theta})d\theta d\bar{\theta} = 0 \]

Proof

By periodicity.

Claim 3

\[ \lim_{\epsilon \to 0} I_{ij} = \begin{cases} -2\pi \rho^2[U(\infty) - U(-\infty)]^2 \int_0^{2\pi} \int_0^{2\pi} \ln |e^{i\theta} - e^{i\bar{\theta}}|Q_{11}(\theta, \bar{\theta})d\theta d\bar{\theta} & i \neq j, \\ 0 \end{cases} \]

\[ \lim_{\epsilon \to 0} I_{ij} = \begin{cases} -2\pi \rho^2[U(\infty) - U(-\infty)]^2 \int_0^{2\pi} \int_0^{2\pi} \ln |e^{i\theta} - e^{i\bar{\theta}}|Q_{22}(\theta, \bar{\theta})d\theta d\bar{\theta} & i \neq j. \end{cases} \]

Proof

We first show that for \( i \neq j \Rightarrow \lim_{\epsilon \to 0} I_{ij} = 0 \)

a) Set

\[ u(\theta) = \int_0^{2\pi} \ln |e^{i\theta} - e^{i\bar{\theta}}| \cos \bar{\theta} d\bar{\theta} \]

We show that \( u(\theta) = u(-\theta) \). From this it follows by cancellation that

\[ \int_0^{2\pi} \int_0^{2\pi} \ln |e^{i\theta} - e^{i\bar{\theta}}|Q_{ij}(\theta, \bar{\theta})d\theta d\bar{\theta} = 0 \]

Indeed, we first observe that (3.24) defines a \( 2\pi \)-periodic function.

We calculate

\[ u(-\theta) = \int_0^{2\pi} \ln |e^{-i\theta} - e^{-i\bar{\theta}}| \cos \bar{\theta} d\bar{\theta} = \int_0^{2\pi} \ln |e^{-i\theta} - e^{-i\bar{\theta}}| \cos \bar{\theta} d\bar{\theta} = \int_0^{2\pi} \ln |e^{i\theta} - e^{i\bar{\theta}}| \cos \bar{\theta} d\bar{\theta} = u(\theta) \]

and the result is obtained.

b) Our aim now, is to show that for \( i = j \Rightarrow \lim_{\epsilon \to 0} I_{11} = \lim_{\epsilon \to 0} I_{22} \)

\[ \int_0^{2\pi} \int_0^{2\pi} \ln |e^{i\theta} - e^{i\bar{\theta}}| \cos \theta \cos \bar{\theta} d\theta d\bar{\theta} = \int_0^{2\pi} \int_0^{2\pi} \ln |e^{i(\theta^* + \bar{\theta}^*)} - e^{i(\theta^* + \bar{\theta}^*)}| \sin \theta^* \sin \bar{\theta}^* d\theta^* d\bar{\theta}^* \]

\[ (\theta^* = \theta - \frac{\pi}{2}, \bar{\theta}^* = \bar{\theta} - \frac{\pi}{2} \text{ by utilizing } 2\pi\text{-periodicity}) \]

\[ = \int_0^{2\pi} \int_0^{2\pi} \ln |e^{i\theta^*} - e^{i\bar{\theta}^*}| \sin \theta^* \sin \bar{\theta}^* d\theta^* d\bar{\theta}^* \]

and hence

\[ \lim_{\epsilon \to 0} I_{11} = \lim_{\epsilon \to 0} I_{22}. \]

**Theorem 3.6**

Let \( a_{ij}^\epsilon \) as in Lemma 3.1. Then the following estimate holds true

\[ a_{ij}^\epsilon = C\rho N \delta_{ij} + O(\rho^{2N-1}) + O(\frac{\epsilon}{\rho}) + O(\epsilon^{2N-1}) \]
as $\epsilon \to 0$, for fixed $\rho$.

**Proof**

Combination of Lemmas 3.1-3.5

where

$$a_{ij}(\xi) = -\int_{\Omega} \int_{\Omega} G(x, y) \frac{\partial u^{\xi}(x)}{\partial \xi_i} \cdot \frac{\partial u^{\xi}(y)}{\partial \xi_j} \, dx \, dy, \; i, j = 1, \ldots, N.$$

The proof of Theorem 3.6 implies from (1.12) the desired result that is: small bubbles for the Cahn-Hilliard are directed towards the closest point on the boundary.

4 Conclusion

Both the conserved Allen-Cahn and the Cahn-Hilliard equation exhibit superslow motion of bubble solutions. They have the same set of equilibria with the same stability property. In both cases the bubble is attracted to the boundary. This happens because the whole evolution takes place so that the free energy $J_{\epsilon}(u(t))$ is monotone in $t$, and that for small $\epsilon$, $J_{\epsilon}$ registers the perimeter of the interface lying inside $\Omega$. Therefore, spheres are the favored intermediate states, while interfaces intersecting the boundary are the favored asymptotic states.

![Figure 3. The dynamic of the energy of the bubble and the half bubble with the same volume](image-url)

It is worth mentioning that the path of the bubble towards the boundary is different in the two cases. In the case of the conserved Allen-Cahn, the bubble sees only the closest point on the boundary and moves towards it by following the segment of minimum distance. In the Cahn-Hilliard case, the bubble interacts with the full boundary and moves towards it by following a path which depends globally on the whole boundary and changes drastically with the size of the bubble. Only, in the limit of bubbles with very small size for the Cahn-Hilliard dynamic, the bubble moves along the segment of the minimal distance as in the Allen-Cahn case.

Appendix A The Proof of Lemma 3.5 for $N > 2$

In this appendix, we generalize the proof of Lemma 3.5 to N dimensions. We have

$$I_{ij} = -\frac{1}{\epsilon^2} \int_{\Omega_x} \int_{\Omega_y} N(|x - y|) \hat{U}(\frac{|x - \xi| - \rho}{\epsilon}) \hat{U}(\frac{|y - \xi| - \rho}{\epsilon}) \cos \theta_i(x) \cos \theta_j(y) dx dy$$

Claim

$$\lim_{\epsilon \to 0} I_{ij} = \frac{\omega_N}{N-2} \rho^{2N-2}[U(\infty) - U(-\infty)]^2 \int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{|x - y|^{N-2}} \cos \theta_i(x) \cos \theta_j(y) dS_x dS_y$$

(A.1)

where $\omega_N$ denotes the surface area of the unit sphere in $\mathbb{R}^N$

$$\cos \theta_i(x) = \frac{x_i - \xi_i}{|x - \xi|}, \cos \theta_j(y) = \frac{y_i - \xi_i}{|y - \xi|}.$$

Verification

We show that

$$\frac{1}{\epsilon} \hat{U}(\frac{|x - \xi| - \rho}{\epsilon}) \to \omega_N \rho^{N-1}[U(\infty) - U(-\infty)] \delta_\rho(|x - \xi|)$$

$$\frac{1}{\epsilon} \hat{U}(\frac{|y - \xi| - \rho}{\epsilon}) \to \omega_N \rho^{N-1}[U(\infty) - U(-\infty)] \delta_\rho(|y - \xi|)$$

Indeed,

(1)

$$\frac{1}{\epsilon} \int_{\mathbb{R}^N} \hat{U}(\frac{|x - \xi| - \rho}{\epsilon}) dx = \frac{1}{\epsilon} \int_{S^{N-1}} \int_{0}^{\infty} \hat{U}(\frac{r - \rho}{\epsilon}) r^{N-1} drdS$$

$$= \frac{1}{\epsilon} \int_{S^{N-1}} \int_{0}^{\infty} \hat{U}(\eta)(\epsilon \eta + \rho)^{N-1} d\eta dS \to \omega_N \int_{0}^{\infty} \hat{U}(\eta) \rho^{N-1} d\eta$$

$$\to \omega_N \rho^{N-1}[U(\infty) - U(-\infty)]$$
We would like to show first that
\[
\frac{1}{\epsilon} \int_{\mathbb{R}^N} \tilde{U}(\frac{|x-\xi|}{\epsilon} - \rho)g(x)dx \to \omega_N \rho^{N-1}[U(\infty) - U(-\infty)] \int_{|y-\xi|=\rho} g(y)dy
\]
We would like to accomplish the following
\[
\lim_{\epsilon \to 0} I_{ij} = C \rho^N \delta_{ij} = \begin{cases} 
0, & \text{when } i \neq j \\
C \rho^N, & \text{when } i = j
\end{cases}
\]
(A) \( i \neq j \)
From Claim it’s enough to show that
\[
\int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{|x-y|^{N-2}} \cos \theta_i(x) \cos \theta_j(y) dS_x dS_y = 0
\]
- We first show that the above integral is well defined. This is true because the singularity exists only when \( x \to y \). So, we fix \( \delta > 0 \) so small that \( |x-y| < \delta, \ x, y \in \mathbb{R}^{N-1} \) and by the following calculation we conclude that the singularity is integrable
\[
\int_{\mathbb{R}^{N-1}} \int_{\mathbb{R}^{N-1}} \frac{1}{|x-y|^{N-2}} dxdy = \int_{\mathbb{R}^{N-1}} \left( \int_{|x-y| < \delta} \frac{1}{|x-y|^{N-2}} dxdy \right) dy = \int_{\mathbb{R}^{N-1}} (\int_{|x-y| < \delta} r^{N-2} dr) dy = \int (\int dr) dy
\]
For \( N = 2 \) the calculation is similar.

From (A.1) we have
\[
\int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{|x-y|^{N-2}} \frac{x_i - \xi_i}{|x-\xi|} \frac{y_j - \xi_j}{|y-\xi|} dS_x dS_y
\]
Set
\[
g(y) = \int_{S^{N-1}} \frac{(x_i - \xi_i)}{|x-\xi|} dS_x
\]
By making the transformation \( y \to y^* \) where \( y^* = (y_1, \ldots, y_i, \ldots, y_{j-1}, -y_j, \ldots) \) the symmetric of \( y = (y_1, \ldots, y_i, \ldots, y_j, \ldots) \) considering the \( x_i \) axis, it is easy to prove that \( g(y^*) = g(y) \). Then by setting
\[
Q(y) = \int_{S^{N-1}} g(y) \frac{(y_j - \xi_j)}{|y-\xi|} dS_y
\]
and calculating \( Q(y^*) \) we take
\[
Q(y^*) = \int_{S^{N-1}} g(y^*) \frac{(-y_j + \xi_j)}{|y-\xi|} dS_y = -\int_{S^{N-1}} g(y) \frac{(y_j - \xi_j)}{|y-\xi|} dS_y = -Q(y)
\]
So,
\[
\int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{|x-y|^{N-2}} \frac{(x_i - \xi_i)}{|x-\xi|} \frac{(y_j - \xi_j)}{|y-\xi|} dS_x dS_y = 0 \Rightarrow \lim_{\epsilon \to 0} I_{ij} = 0
\]
(B) \( i = j \)
We would like to show first that
\[
R_{11} = R_{22} = \ldots = R_{NN}
\]
where
\[
R_{ii} = \int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{|x-y|^{N-2}} \frac{(x_i - \xi_i)}{|x-\xi|} \frac{(y_i - \xi_i)}{|y-\xi|} dS_x dS_y, \quad i = 1, \ldots, N
\]
By applying the transformation

\[ u - \xi \rightarrow (x_i - \xi_i, \ldots, x_1 - \xi_1, \ldots, x_N - \xi_N) \]

\[ v - \xi \rightarrow (y_i - \xi_i, \ldots, y_1 - \xi_1, \ldots, y_N - \xi_N) \]

we have

\[ R_{ii} = \int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{|x-y|^{N-2}} \frac{(x_i - \xi_i) (y_i - \xi_i)}{|x-\xi| |y-\xi|} dS_x dS_y \]

\[ = \int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{|u-v|^{N-2}} \frac{(u_i - \xi_i) (v_i - \xi_i)}{|u-\xi| |v-\xi|} dS_u dS_v = R_{ii} \]

where we utilized that \( f \) is an orthogonal transformation. By utilizing \( R_{11} = R_{22} = \ldots = R_{NN} \) it is obvious that

\[ R_{ii} = \frac{1}{N} \sum_{i=1}^{N} R_{ii} \]

\[ \int_{S^{N-1}} \int_{S^{N-1}} \frac{x_i - \xi_i}{|x-\xi|} \frac{y_j - \xi_j}{|y-\xi|} dS_x dS_y = \frac{1}{\rho^2} R_{ii} \]

We sum up all the \( R_{ii} \)'s and we calculate

\[ \frac{1}{\rho^2} \sum_{i=1}^{N} R_{ii} = \frac{1}{\rho^2} \int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{|x-y|^{N-2}} < x - \xi, y - \xi > dS_x dS_y \]

\[ = \frac{1}{\rho^2} \int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{|x-y|^{N-2}} ||x - \xi|| \cdot ||y - \xi|| \cos \theta dS_x dS_y = \frac{1}{\rho^2} \int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{|x-y|^{N-2}} \rho^2 \cos \theta dS_x dS_y \]

\[ = \int_{S^{N-1}} \int_{S^{N-1}} \frac{1}{\rho^{N-2}} \frac{1}{(2-2 \cos \theta)^{N-2}} \cos \theta dS_x dS_y = \frac{1}{\rho^{N-2}} \int_{S^{N-1}} \int_{S^{N-1}} \frac{\cos \theta}{(2-2 \cos \theta)^{N-2}} dS_x dS_y \neq 0 \]

By Claim, we conclude

\[ \lim_{\epsilon \to 0} I_{ij} = \frac{\omega N}{N-2} \rho^{2N-2} \frac{1}{\rho^{N-2}} \frac{1}{N} \left[ U(\infty) - U(-\infty) \right]^2 \int_{S^{N-1}} \int_{S^{N-1}} \frac{\cos \theta}{(2-2 \cos \theta)^{N-2}} dS_x dS_y \]

\[ = \frac{\omega N}{N-2} \rho^{2N} \frac{1}{N} \left[ U(\infty) - U(-\infty) \right]^2 \int_{S^{N-1}} \int_{S^{N-1}} \frac{\cos \theta}{(2-2 \cos \theta)^{N-2}} dS_x dS_y \]

where \( \int_{S^{N-1}} \frac{\cos \theta}{(2-2 \cos \theta)^{N-2}} dS_x \neq 0 \).
